1. Abstract

The growing interest in computer vision of the past decade. Fueled by the steady doubling rate of computing power every 13 months, face detection and recognition has transcended from an esoteric to a popular area of research in computer vision and one of the better and successful applications of image analysis and **algorithm-based** understanding. Because of the intrinsic nature of the problem, computer vision is not only a computer science area of research, but also the object of neuro-scientific and psychological studies, mainly because of the general opinion that advances in computer image processing and understanding research will provide insights into how our brain work and vice versa. Because of general curiosity and interest in the matter, the author has proposed to create an application that would allow user access to a particular machine based on an in-depth analysis of a person's facial features.

2. Introduction

Face detection is a computer vision technology that helps to locate/visualize human faces in digital images. This technique is a specific use case of object detection technology that deals with detecting instances of semantic objects of a certain class (such as humans, buildings or cars) in digital images and videos. With the advent of technology, face detection has gained a lot of importance especially in fields like photography, security, and marketing. Face detection using Haar cascades is a machine learning based approach where a cascade function is trained with a set of input data. OpenCV already contains many pre-trained classifiers for face, eyes, smiles, etc.. We will be using the face classifier. You can experiment with other classifiers as well.

3. OpenCV-Python

3.1. Overview

OpenCV was started at Intel in the year 1999 by **Gary Bradsky**. The first release came a little later in the year 2000. OpenCV essentially stands for **Open Source Computer Vision Library**. Although it is written in optimized C/C++, it has interfaces for Python and Java along with C++. OpenCV boasts of an active user base all over the world with its use increasing day by day due to the surge in computer vision applications.

OpenCV-Python is the python API for OpenCV. You can think of it as a python wrapper around the C++ implementation of OpenCV. OpenCV-Python is not only fast (since the background consists of code written in C/C++) but is also easy to code and deploy (due to the Python wrapper in foreground). This makes it a great choice to perform computationally intensive programs.

3.2. Installation

OpenCV-Python supports all the leading platforms like Mac OS, Linux, and Windows. Packages for standard desktop environments (Windows, macOS, almost any GNU/Linux distribution)

- run `pip install opencv-python` if you need only main modules
- run `pip install opencv-contrib-python` if you need both main and contrib modules.

4. Images as Arrays

An image is nothing but a standard Numpy array containing pixels of data points. More the number of pixels in an image, the better is its resolution. You can think of pixels to be tiny blocks of information arranged in the form of a 2 D grid, and the depth of a pixel refers to the color information present in it. In order to be processed by a computer, an image needs to be converted into a binary form. The color of an image can be calculated as follows:

Number of colors/ shades = 2^{bpp} where bpp represents bits per pixel

Naturally, more the number of bits/pixels, more possible colors in the images. The following table shows the relationship more clearly.

Bits/Pixel	Possible colours
1	$2^1 = 2$
2	$2^2 = 4$
3	$2^3 = 8$
4	$2^4 = 16$
8	$2^8 = 256$
16	$2^{16} = 65000$

Let us now have a look at the representation of the different kinds of images:

4.1. Binary Image

A binary image consists of 1 bit/pixel and so can have only two possible colors, i.e., black or white. Black is represented by the value 0 while 1 represents white.

Representation of a black and white image in form of a binary where '1' represents pure white while '0' represents black. Here the image is represented by 1 bit/pixel which means image can be represented by only 2 possible colours since $2^1 = 2$

4.2. Grayscale image

A grayscale image consists of 8 bits per pixel. This means it can have 256 different shades where 0 pixels will represent black color while 255 denotes white. For example, the image below shows a grayscale image represented in the form of an array. A grayscale image has only 1 channel where the channel represents dimension.

4.3. Colored image

Colored images are represented as a combination of Red, Blue, and Green, and all the other colors can be achieved by mixing these primary colors in correct proportions.

source

A colored image also consists of 8 bits per pixel. As a result, 256 different shades of colors can be represented with 0 denoting black and 255 white. Let us look at the famous colored image of a mandrill which has been cited in many image processing examples.

If we were to check the shape of the image above, we would get:

Shape
(288, 288, 3)
288: Pixel width
288: Pixel height
3: color channel

This means we can represent the above image in the form of a three-dimensional array.

5. Images and OpenCV

Before we jump into the process of face detection, let us learn some basics about working with OpenCV. In this section we will perform simple operations on images using OpenCV like opening images, drawing simple shapes on images and interacting with images through callbacks. This is necessary to create a foundation before we move towards the advanced stuff.

5.1. Importing Images in OpenCV

5.1.1. Using Jupyter notebooks

Steps:

- **Import the necessary libraries**

```
import numpy as np
import cv2
import matplotlib.pyplot as plt
%matplotlib inline
```

- Read in the image using the **imread** function.

```
img_raw = cv2.imread('image.jpg')
```

- **The type and shape of the array.**

```
type(img_raw)
numpy.ndarray
img_raw.shape
(1300, 1950, 3)
```

Thus, the .png image gets transformed into a numpy array with a shape of 1300x1950 and has 3 channels.

- viewing the image

```
plt.imshow(img_raw)
```

What we get as an output is a bit different concerning color. We expected a bright colored image but what we obtain is an image with some bluish tinge. That happens because OpenCV and matplotlib have different orders of primary colors. Whereas OpenCV reads images in the form of BGR, matplotlib, on the other hand, follows the order of RGB. Thus, when we read a file through OpenCV, we read it as if it contains channels in the order of blue, green and red. However, when we display the image using matplotlib, the red and blue channel gets swapped and hence the blue tinge. To avoid this issue, we will transform the channel to how matplotlib expects it to be using the `cvtColor` function.

```
img = cv2.cvtColor(img_raw, cv2.COLOR_BGR2RGB)  
plt.imshow(img_rgb)
```

5.1.2. Using Python Scripts

```
import cv2
img = cv2.imread('image.jpg')
while True:
    cv2.imshow('mandrill',img)

    if cv2.waitKey(1) & 0xFF == 27:
        break
```

```
cv2.destroyAllWindows()
```

In this code, we have a condition, and the image will only be shown if the condition is true. Also, to break the loop, we will have two conditions to fulfill:

- The `cv2.waitKey()` is a keyboard binding function. Its argument is the time in milliseconds. The function waits for specified milliseconds for any keyboard event. If you press any key in that time, the program continues.

- The second condition pertains to the pressing of the Escape key on the keyboard. Thus, if 1 millisecond has passed and the escape key is pressed, the loop will break and program stops.
- `cv2.destroyAllWindows()` simply destroys all the windows we created. If you want to destroy any specific window, use the function `cv2.destroyWindow()` where you pass the exact window name as the argument.

5.2. Savings images

The images can be saved in the working directory as follows:

```
cv2.imwrite('final_image.png',img)
```

Where the `final_image` is the name of the image to be saved.

5.3. Basic Operations on Images

In this section, we will learn how we can draw various shapes on an existing image to get a flavor of working with OpenCV.

5.3.1. Drawing on Images

- Begin by importing necessary libraries.

```
import numpy as np
import matplotlib.pyplot as plt
%matplotlib inline
import cv2
```

- Create a black image which will act as a template.

```
image_blank = np.zeros(shape=(512,512,3),dtype=np.int16)
```

- Display the black image.

```
plt.imshow(image_blank)
```

```
: <matplotlib.image.AxesImage at 0x123141160>
```

5.3.1.1. Function & Attributes

The generalised function for drawing shapes on images is:

```
cv2.shape(line, rectangle etc)(image,Pt1,Pt2,color,thickness)
```

There are some common arguments which are passed in function to draw shapes on images:

- Image on which shapes are to be drawn
- co-ordinates of the shape to be drawn from Pt1(top left) to Pt2(bottom right)
- **Color:** The color of the shape that is to be drawn. It is passed as a tuple, eg: (255,0,0). For grayscale, it will be the scale of brightness.
- The thickness of the geometrical figure.

1. Straight Line

Drawing a straight line across an image requires specifying the points, through which the line will pass.

```
# Draw a diagonal red line with thickness of 5 px
```

```
line_red = cv2.line(img,(0,0),(511,511),(255,0,0),5)  
plt.imshow(line_red)
```

```
# Draw a diagonal green line with thickness of 5 px
```

```
line_green = cv2.line(img,(0,0),(511,511),(0,255,0),5)  
plt.imshow(line_green)
```

2. Rectangle

For a rectangle, we need to specify the top left and the bottom right coordinates.

```
#Draw a blue rectangle with a thickness of 5 px
```

```
rectangle= cv2.rectangle(img,(384,0),(510,128),(0,0,255),5)  
plt.imshow(rectangle)
```

3. Circle

For a circle, we need to pass its center coordinates and radius value. Let us draw a circle inside the rectangle drawn above

```
img = cv2.circle(img,(447,63), 63, (0,0,255), -1) # -1 corresponds to a filled circle  
plt.imshow(circle)
```

5.3.2. Writing on Images

Adding text to images is also similar to drawing shapes on them. But you need to specify certain arguments before doing so:

- Text to be written
- coordinates of the text. The text on an image begins from the bottom left direction.
- Font type and scale.
- Other attributes like color, thickness and line type. Normally the line type that is used is `lineType = cv2.LINE_AA`.

```
font = cv2.FONT_HERSHEY_SIMPLEX  
text = cv2.putText(img,'OpenCV',(10,500), font, 4,(255,255,255),2,cv2.LINE_AA)  
plt.imshow(text)
```

These were the minor operations that can be done on images using OpenCV. Feel free to experiment with the shapes and text.

6. Face Detection

6.1. Overview

Face detection is a technique that identifies or locates human faces in digital images. A typical example of face detection occurs when we take photographs through our smartphones, and it instantly detects faces in the picture. Face detection is different from Face recognition. Face detection detects merely the presence of faces in an image while facial recognition involves identifying whose face it is. In this article, we shall only be dealing with the former.

Face detection is performed by using classifiers. A classifier is essentially an algorithm that decides whether a given image is positive(face) or negative(not a face). A classifier needs to be trained on thousands of images with and without faces. Fortunately, OpenCV already has two pre-trained face detection classifiers, which can readily be used in a program. The two classifiers are:

- Haar Classifier and
- Local Binary Pattern(LBP) classifier.

In this project, however, we will only discuss the Haar Classifier.

6.2. Haar feature-based cascade classifiers

Haar-like features are digital image features used in object recognition. They owe their name to their intuitive similarity with Haar wavelets and were used in the first real-time face detector. **Paul Viola** and **Michael Jones** in their paper titled "Rapid Object Detection using a Boosted Cascade of Simple Features" used the idea of Haar-feature classifier based on the Haar wavelets.

This classifier is widely used for tasks like face detection in computer vision industry.

Haar cascade classifier employs a machine learning approach for visual object detection which is capable of processing images extremely rapidly and achieving high detection rates. This can be attributed to three main reasons:

- Haar classifier employs '*Integral Image*' concept which allows the features used by the detector to be computed very quickly.
- The learning algorithm is based on *AdaBoost*. It selects a small number of important features from a large set and gives highly efficient classifiers.
- More complex classifiers are combined to form a '*cascade*' which discard any non-face regions in an image, thereby spending more computation on promising object-like regions.

Let us now try and understand how the algorithm works on images in steps:

6.2.1. 'Haar features' extraction

After the tremendous amount of training data (in the form of images) is fed into the system, the classifier begins by extracting Haar features from each image. Haar Features are kind of convolution kernels which primarily detect whether a suitable feature is present on an image or not. Some examples of Haar features are mentioned below:

source

These Haar Features are like windows and are placed upon images to compute a single feature. The feature is essentially a single value obtained by subtracting the sum of the pixels under the white region and that under the black. The process can be easily visualized in the example below.

For demonstration purpose, let's say we are only extracting two features, hence we have only two windows here. The first feature relies on the point that the eye region is darker than the adjacent cheeks and nose region. The second feature focuses on the fact that eyes are kind of darker as compared to the bridge of the nose. Thus, when the feature window moves over the eyes,

it will calculate a single value. This value will then be compared to some threshold and if it passes that it will conclude that there is an edge here or some positive feature.

6.2.2. 'Integral Images' concept

The algorithm proposed by Viola Jones uses a 24X24 base window size, and that would result in more than 180,000 features being calculated in this window. Imagine calculating the pixel difference for all the features? The solution devised for this computationally intensive process is to go for the **Integral Image** concept. The integral image means that to find the sum of all pixels under any rectangle, we simply need the four corner values.

Integral image

$$\begin{aligned} \text{Sum of all pixels in} \\ D &= 1+4-(2+3) \\ &= A+(A+B+C+D)-(A+C+A+B) \\ &= D \end{aligned}$$

source

This means, to calculate the sum of pixels in any feature window, we do not need to sum them up individually. All we need is to calculate the integral image using the 4 corner values. The example below will make the process transparent.

31	2	4	33	5	36
12	26	9	10	29	25
13	17	21	22	20	18
24	23	15	16	14	19
30	8	28	27	11	7
1	35	34	3	32	6

31	33	37	70	75	111
43	71	84	127	161	222
56	101	135	200	254	333
80	148	197	278	346	444
110	186	263	371	450	555
111	222	333	444	555	666

$$15 + 16 + 14 + 28 + 27 + 11 = 101 + 450 - 254 - 186 = 111$$

source

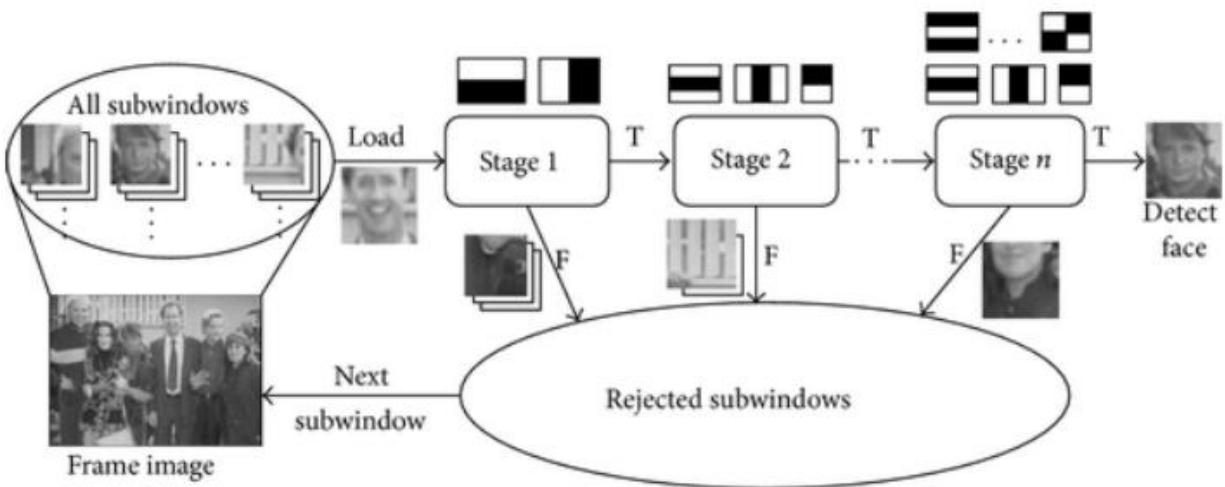

6.2.3. 'Adaboost' : to improve classifier accuracy

As pointed out above, more than 180,000 features values result within a 24X24 window. However, not all features are useful for identifying a face. To only select the best feature out of the entire chunk, a machine learning algorithm called **Adaboost** is used. What it essentially does is that it selects only those features that help to improve the classifier accuracy. It does so by constructing a strong classifier which is a linear combination of a number of weak classifiers. This reduces the amount of features drastically to around 6000 from around 180,000.

6.2.4. Using 'Cascade of Classifiers'

Another way by which Viola Jones ensured that the algorithm performs fast is by employing a **cascade of classifiers**. The cascade classifier essentially consists of stages where each stage consists of a strong classifier. This is beneficial since it eliminates the need to apply all features at once on a

window. Rather, it groups the features into separate sub-windows and the classifier at each stage determines whether or not the sub-window is a face. In case it is not, the sub-window is discarded along with the features in that window. If the sub-window moves past the classifier, it continues to the next stage where the second stage of features is applied. The process can be understood with the help of the diagram below.

Cascade structure for Haar classifiers.

6.3. Face Detection with OpenCV-Python

Now we have a fair idea about the intuition and the process behind Face recognition. Let us now use OpenCV library to detect faces in an image.

Load the necessary Libraries

```
import numpy as np
import cv2
import matplotlib.pyplot as plt
%matplotlib inline
```

Loading the image to be tested in grayscale

```
#Loading the image to be tested
test_image = cv2.imread('data/baby1.jpg')
```

```
#Converting to grayscale
test_image_gray = cv2.cvtColor(test_image, cv2.COLOR_BGR2GRAY)
```

```
# Displaying the grayscale image
plt.imshow(test_image_gray, cmap='gray')
```

Since we know that OpenCV loads an image in BGR format, so we need to convert it into RGB format to be able to display its true colors. Let us write a small function for that.

Since we know that OpenCV loads an image in BGR format, so we need to convert it into RGB format to be able to display its true colors. Let us write a small function for that.

```
def convertToRGB(image):
    return cv2.cvtColor(image, cv2.COLOR_BGR2RGB)
```

Haar cascade files

OpenCV comes with a lot of pre-trained classifiers. For instance, there are classifiers for smile, eyes, face, etc. These come in the form of xml files and are located in the `opencv/data/haarcascades/` folder. However, to make things simple, you can also access them from [here](#). Download the xml files and place them in the data folder in the same working directory as the jupyter notebook.

Loading the classifier for frontal face

```
haar_cascade_face =  
cv2.CascadeClassifier('data/haarcascade/haarcascade_frontalface_default.xml')
```

Face detection

We shall be using the **detectMultiscale** module of the classifier. This function will return a rectangle with coordinates(x,y,w,h) around the detected face. This function has two important parameters which have to be tuned according to the data.

- **scalefactor** In a group photo, there may be some faces which are near the camera than others. Naturally, such faces would appear more prominent than the ones behind. This factor compensates for that.
- **minNeighbors** This parameter specifies the number of neighbors a rectangle should have to be called a face. You can read more about it [here](#).

```
faces_rects = haar_cascade_face.detectMultiScale(test_image_gray, scaleFactor = 1.2,  
minNeighbors = 5);
```

```
# Let us print the no. of faces found  
print('Faces found: ', len(faces_rects))
```

```
Faces found: 1
```

Our next step is to loop over all the coordinates it returned and draw rectangles around them using Open CV. We will be drawing a green rectangle with a thickness of 2

```
for (x,y,w,h) in faces_rects:  
    cv2.rectangle(test_image, (x, y), (x+w, y+h), (0, 255, 0), 2)
```

Finally, we shall display the original image in colored to see if the face has been detected correctly or not.

```
#convert image to RGB and show image
```

```
plt.imshow(convertToRGB(test_image))
```

Here, it is. We have successfully detected the face in the picture. Let us now create a generalized function for the entire face detection process.

Face Detection with generalized function

```
def detect_faces(cascade, test_image, scaleFactor = 1.1):  
    # create a copy of the image to prevent any changes to the original one.  
    image_copy = test_image.copy()  
  
    #convert the test image to gray scale as opencv face detector expects gray images  
    gray_image = cv2.cvtColor(image_copy, cv2.COLOR_BGR2GRAY)  
  
    # Applying the haar classifier to detect faces  
    faces_rect = cascade.detectMultiScale(gray_image, scaleFactor=scaleFactor,  
                                          minNeighbors=5)  
  
    for (x, y, w, h) in faces_rect:  
        cv2.rectangle(image_copy, (x, y), (x+w, y+h), (0, 255, 0), 15)  
  
    return image_copy
```

Testing the function on new image

This time test image is as follows:

```
#loading image
test_image2 = cv2.imread('baby2.jpg')

# Converting to grayscale
test_image_gray = cv2.cvtColor(test_image, cv2.COLOR_BGR2GRAY)

# Displaying grayscale image
plt.imshow(test_image_gray, cmap='gray')

#call the function to detect faces
faces = detect_faces(haar_face_cascade, test_image2)

#convert to RGB and display image
plt.imshow(convertToRGB(faces))
```

6.4. Face Recognition Process

For this project three algorithms are implemented independently. These are Eigenface, Fisher face and Linear binary pattern histograms respectively. All three can be implemented using OpenCV libraries.

There are three stages for the face recognition as follows:

1. Collecting images IDs
2. Extracting unique features, classifying them and storing in XML files
3. Matching features of an input image to the features in the saved XML files and predict identity

6.4.1 Collecting the image data

Collecting classification images is usually done manually using a photo editing software to crop and resize photos. Furthermore, PCA and LDA requires the same number of pixels in all the images for the correct operation. This time consuming and a laborious task is automated through an application to collect 100 images with different expressions. The application detects suitable expressions between 300ms, straightens any existing tilt and

save them. Application starts with a request for a name to be entered to be stored with the ID in a text file. The face detection system starts the first half. However, before the capturing begins, the application check for the brightness levels and will capture only if the face is well illuminated. Furthermore, after the face is detected, the position of the eyes is analyzed. If the head is tilted, the application automatically corrects the orientation. These two additions were made considering the requirements for Eigenface algorithm. The Image is then cropped and saved using the ID as a filename to be identified later. A loop runs this program until 100 viable images are collected from the person. This application made data collection efficient.

```
face_classifier = cv2.CascadeClassifier('C:/Users/Rajat/Anaconda3/Lib/site-packages/cv2/data/haarcascade_frontalface_alt.xml')

def face_extractor(img):

    gray = cv2.cvtColor(img,cv2.COLOR_BGR2GRAY)
    faces = face_classifier.detectMultiScale(gray,1.3,5)

    if faces is():
        return None

    for(x,y,w,h) in faces:
        cropped_face = img[y:y+h, x:x+w]

    return cropped_face

cap = cv2.VideoCapture(0)
count = 0
while True:
    ret, frame = cap.read()
    if face_extractor(frame) is not None:
        count+=1
        face = cv2.resize(face_extractor(frame),(200,200))
        face = cv2.cvtColor(face, cv2.COLOR_BGR2GRAY)

        file_name_path = 'E:/python/Open CV face detector/faces/user'+str(count)+'.jpg'
        cv2.imwrite(file_name_path,face)

        cv2.putText(face,str(count),(50,50),cv2.FONT_HERSHEY_COMPLEX,1,(0,255,0),2)
        cv2.imshow('Face Cropper', face)
    else:
        print("Face not Found")
        pass

    if cv2.waitKey(1)==13 or count==100:
        break

cap.release()
cv2.destroyAllWindows()
print('Colleting Samples Complete!!!')
```

!00 images has been stored.

6.4.2 Training the Classifiers

OpenCV enables the creation of XML files to store features extracted from datasets using the FaceRecognizer class. The stored images are imported, converted to grayscale and saved with IDs in two lists with same indexes. FaceRecognizer objects are created using face recognizer class. Each recognizer can take in parameters that are described below

cv2.face.createLBPHFaceRecognizer_create()

1. The radius from the center pixel to build the local binary pattern.
2. The Number of sample points to build the pattern. Having a considerable number will slow down the computer.
3. The Number of Cells to be created in X axis.
4. The number of cells to be created in Y axis.
5. A threshold value similar to Eigenface and Fisherface. if the threshold is passed the object will return -1.

Recognizer objects are created and images are imported, resized, converted into NumPy arrays and stored in a vector. The ID of the image is gathered from splitting the file name, and stored in another vector. By using FaceRecognizer.train(NumPy Image, ID) all three of the objects are trained. It must be noted that resizing the images were required only for Eigenface and Fisherface, not for LBPH. Next, the configuration model is saved as a XML file using FaceRecognizer.save(FileName). In this project, all three are trained and saved through one application for convenience.

```

from os import listdir
from os.path import isfile, join

data_path = 'E:/python/Open CV face detector/faces/'
onlyfiles = [f for f in listdir(data_path) if isfile(join(data_path,f))]

Training_Data, Labels = [], []

for i, files in enumerate(onlyfiles):
    image_path = data_path + onlyfiles[i]
    images = cv2.imread(image_path, cv2.IMREAD_GRAYSCALE)
    Training_Data.append(np.asarray(images, dtype=np.uint8))
    Labels.append(i)

Labels = np.asarray(Labels, dtype=np.int32)

model = cv2.face.LBPHFaceRecognizer_create()

model.train(np.asarray(Training_Data), np.asarray(Labels))

print("Model Training Complete!!!!")

face_classifier = cv2.CascadeClassifier('C:/Users/Rajat/Anaconda3/Lib/site-packages/cv2/data/haarcascade_frontalface_alt.xml')

Model Training Complete!!!!

```

6.4.3. The Face Recognition

Face recognizer object is created using the desired parameters. Face detector is used to detect faces in the image, cropped and transferred to be recognized. This is done using the same technique used for the image capture application. For each face detected, a prediction is made using FaceRecognizer.predict() which return the ID of the class and confidence. The process is same for all algorithms and if the confidence his higher than the set threshold, ID is -1. Finally, names from the text file with IDs are used to display the name and confidence on the screen. If the ID is -1, the application will print unknown face without the confidence level.

```

def face_detector(img, size = 0.5):
    gray = cv2.cvtColor(img, cv2.COLOR_BGR2GRAY)
    faces = face_classifier.detectMultiScale(gray,1.3,5)

    if faces is():
        return img,[]

    for(x,y,w,h) in faces:
        cv2.rectangle(img, (x,y),(x+w,y+h),(0,255,255),2)
        roi = img[y:y+h, x:x+w]
        roi = cv2.resize(roi, (200,200))

    return img,roi

```

6.4.4 Calibrating the Trainer and Testing on Video

The Trainer (Trainer-All.py) application is used to train and recognizer (Recogniser-All.py) is used for testing the results. The image pairs shown below are with and without calibration of the trainer. All images are taken through video via Microsoft WebCam camera.

```
cap = cv2.VideoCapture(0)
while True:

    ret, frame = cap.read()

    image, face = face_detector(frame)

    try:
        face = cv2.cvtColor(face, cv2.COLOR_BGR2GRAY)
        result = model.predict(face)

        if result[1] < 500:
            confidence = int(100*(1-(result[1])/300))
            display_string = str(confidence)+'% Confidence it is user'
            cv2.putText(image,display_string,(100,120), cv2.FONT_HERSHEY_COMPLEX,1,(250,120,255),2)

            if confidence > 75:
                cv2.putText(image, "Unlocked", (250, 450), cv2.FONT_HERSHEY_COMPLEX, 1, (0, 255, 0), 2)
                cv2.imshow('Face Cropper', image)

            else:
                cv2.putText(image, "Locked", (250, 450), cv2.FONT_HERSHEY_COMPLEX, 1, (0, 0, 255), 2)
                cv2.imshow('Face Cropper', image)

        except:
            cv2.putText(image, "Face Not Found", (250, 450), cv2.FONT_HERSHEY_COMPLEX, 1, (255, 0, 0), 2)
            cv2.imshow('Face Cropper', image)
            pass

        if cv2.waitKey(1)==13:
            break

cap.release()
cv2.destroyAllWindows()
```

7. Result

The collected images are shown below. The face has 100 images. Three applications were written to iterate through the parameters of each algorithm. On each iteration, the algorithm is trained using different parameters and tested against a photo. The resulting data is plotted at the after finishing the tests.

Result 1: - It detects the face and prints the confidence level or accuracy percentage of the user, which is based on test data.

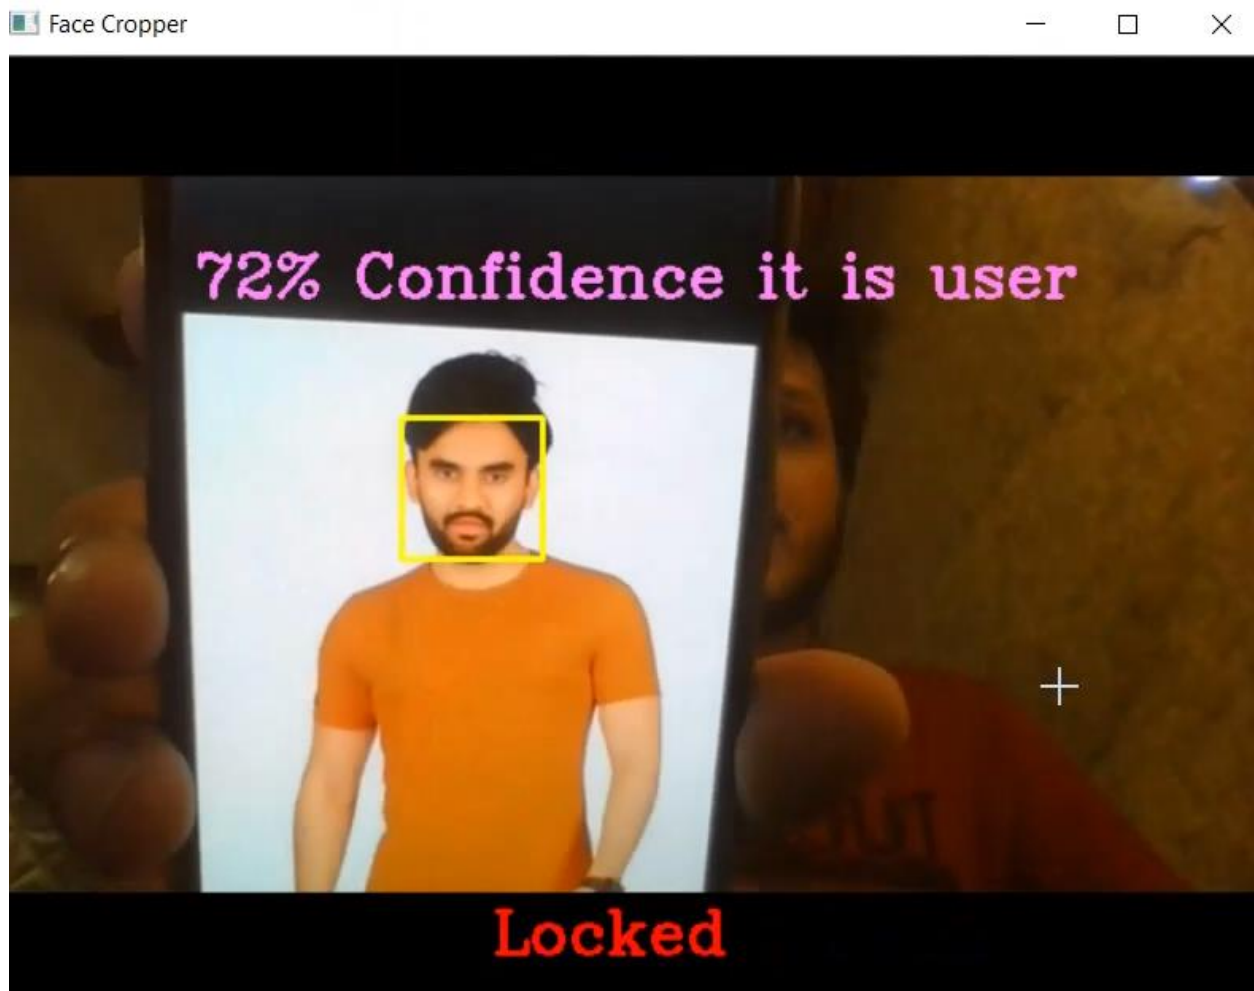

Result 2: - If user covers the face or change the camera angle, it prints out that no face has been found.

Result 3: -If user uses multiple faces, it detects all of the and responds according to the most match.

Result 4: - If the user uses any other face it displays “LOCKED”
